ABSTRACT

When electricity is stolen from distribution networks, non-technical losses (NTLs) have a negative impact on the quality of power supply and lower operating profits. Convolutional neural networks (CNNs) and random forests (RFs) are used in this research to help utility firms deal with the issues of wasteful electricity inspection and unpredictable power use. Attribute variations at different times of the day and on certain days can be learned using convolutional neural networks (CNN) that condense and downsample vast amounts of data from smart meters During training, strategies such as back propagation and a dropout layer are used to prevent the network from being overfit. After then, the RF is taught to look for signs that a customer is attempting to steal electricity using the information it has gleaned. A grid search algorithm can be used to optimize the RF parameters of a hybrid model. To illustrate that the proposed detection strategy is more accurate and efficient than current methods, actual energy usage data is used.

1.INTRODUCTION

Purpose:

The reduction of energy loss in electricity transmission and distribution is a serious concern for power suppliers all over the world. One of the most prevalent ways energy is wasted is through technical and non-technical losses (NTLs). Fraudulent acts involving energy may result in lower profits for power firms.

The use of a CNN to extract features from highresolution smart-meter data piques our interest in detecting electricity theft. This study uses convolutional neural networks (CNNs) to investigate how electricity is stolen from smart grids. As in a traditional single hidden layer feedforward neural network (SLFN), backpropagation is utilized to train the softmax classifier layer in a basic CNN. A decline in the SLFN's ability to generalize is possible when utilizing the backpropagation technique.

Scope:

The Goal of the Initiative Several methods exist for obtaining free electricity, causing the utility provider to suffer a loss of revenue. CNN data from smart meters is critical to the power theft detection model's operation since it automatically collects many aspects of customer usage behaviors. It is used as a replacement for the softmax classifier to improve

detection performance. Customers' real-world data from Ireland and London's energy utilities was used to develop and test this model.

II.LITERATURE SURVEY

Technical and nontechnical losses in power system and its economic consequence in Indian economy

AUTHORS: J. P. Navani, N. K. Sharma, and S. Sapra,

ABSTRACT : Electricity shortages are a widespread problem in India, and they are only getting worse. These shortages have had a negative impact on the country's overall economic growth. The overall loss is equal to the sum of the distribution system's technical and non-technical losses. Large losses can be attributed to a lack of transmission and distribution (T&D), excessive transformation processes, inappropriate load distribution, and significant rural electrification. In the simplest terms, metered electricity losses can be described as the time-varying discrepancy between meter readings taken from the distribution network and those taken from other meters in the building. Technical losses in an electrical system include network impedance, current flows, and auxiliary power. Technical losses may be directly linked to network investment or network functioning. Thieves and unbilled accounts are just two of the many non-technical losses that might occur, as well as inaccuracies in metering and estimations of non-metered consumption. Analyzing power system losses through case studies and MATLAB simulations is one of the primary objectives of this work.

2.2 A framework for enhanced metering systems to detect energy theft using several sensors,

S. McLaughlin, B. Holbert, A. Fawaz, R. Berthier, and S. Zonouz are the authors of this book.

The smart grid's advanced metering infrastructure (AMI) replaces analog devices with computerized smart meters, making it a critical component of the system. As a result of the widespread adoption of smart meters, AMI has become a prime target for energy theft via remote attacks and local physical tampering. For the most part, the many sensors and data sources that smart meters use to detect energy theft are ineffective because they produce many false positives. Our AMIDS intrusion detection system leverages sensor and smart meter data fusion to better identify energy theft, and we describe it in this paper. AMIDS models and detects theft-related behavior more accurately by combining meter audit logs and consumption data from physical and cyber events. AMIDS is able to accurately detect energy theft based on our experiments with normal and abnormal load profiles. More fundamental analyses incorrectly labeled as malicious legitimate changes to the load profile that AMIDS accurately assessed as such.

Smart grid security and privacy issues P. McDaniel and S. McLaughlin are the authors.

This is one of the most significant shifts in the history of the electrical grid—the transition to smart grid technologies. With this new infrastructure, consumers and energy providers can better control and create electricity. The smart grid, like many new technologies, raises new questions about security. Ongoing smart grid installations around the world are examined here in terms of the reasons they are being implemented and the potential consequences of failures in security. Future projects may address the security issues that may be faced by future deployments.

Nontechnical loss detection using artificial intelligence is difficult, according to a new survey.

P. Glauner, J. A. Meira, P. Valtchev, R. State, and F. Bettinger are the authors of this article.

ABSTRACT: Researchers in electrical engineering and computer science are becoming increasingly interested in detecting non-technical losses (NTL), such as electricity theft, defective meters, or billing problems. NTLs have a considerable negative impact on the economy, as they account for up to 40% of the total electricity provided in some countries. There is a strong focus on using artificial intelligence to determine if a consumer is responsible for NTL. NTL definitions and economic effects, such as decreased revenue and profit for energy providers as well as decreased grid stability and reliability, are briefly discussed in this study. After that, it takes a look at the most recent and most thorough research on the methods, features, and data sets that have been used. There are still many scientific and engineering obstacles to overcome before NTL detection can be improved. State estimation and variance analysis for non-technical loss detection

III.SYSTEM ANALYSIS

EXISTING SYSTEM:

Existing machine learning methods include classification and clustering models. However, despite the uniqueness and impressiveness of the machine learning detection algorithms discussed above, their performance is still insufficient for practical use. Most of these methods need manual feature extraction due to their limited ability to handle high-dimensional data. It's true that the average consumption data includes the mean, standard deviation, maximum, and minimum. There are no manual methods for extracting the 2D properties of smart meter data because they are time-consuming and tiresome.

The existing system's drawbacks are detailed in this section.

The performances are still not excellent enough to allow for practice.

Time-consuming and can't gather 2D characteristics from smart meter data.

PROPOSED SYSTEM:

Utilities will be provided with a ranked list of its clients, according to the likelihood that they have an anomaly in their electric meters, through this process. Figure 1 depicts the three primary steps of the electricity theft detecting system:

To better understand why a CNN is employed for feature extraction, let's look at the factors that affect how people utilize electricity. Data cleaning (resolving outliers), missing value imputation, and data transformation are all part of data preprocessing (normalization).

Using cross-validation, we partition the preprocessed dataset into train and test datasets to assess how well the methods in this paper perform.

WHY THE PROPOSED SYSTEM IS ADVANTAGEOUS

To determine whether or not a customer is stealing electricity.

IV.SYSTEM DESIGN

Block Diagram

Architecture

FLOWCHART

Flow of electricity theft detection.

IMPLEMENTATION:

MODULES:

The following steps are being taken by the author of the proposed paper:

Using this module, you may read the power consumption data.

2) Normalize and clean dataset: in this module, we will remove missing dataset and normalize the dataset.

(3) Train the CNN Model: Using this module, we'll develop a theft prediction model by training CNN using a dataset, then extracting trained features from CNN and feeding them into the random forest algorithm. We've implemented a DROPOUT layer to get rid of superfluous functionality.

To calculate precision, recall, FSCORE, and accuracy, we'll use this module to train Random Forest with CNN features.

Use this module to train SVM with CNN features, and then calculate precision, recall, FSCORE, and accuracy using the CNN features as inputs.

On a typical dataset, we trained a random forest without CNN features and then calculated precision, recall, FSCORE, and accuracy. 6) Train Random Forest without CNN:

Predictive modeling with SVM rather than CNN: We performed this analysis by first training the SVM on a typical dataset without incorporating CNN characteristics.

8) Graph of Comparison: we will use this to provide a graph of comparison of all methods.

In this module, we upload test data and CNN-RF makes a prediction about whether or not the records contain ENERGY THEFT.

Algorithms:

A single layer of a neural network with sigmoid activation is equal to a logistic regression model for binary classification. The sigmoid function that emerges from linear regression has a range of 0 to 1 points. Aberrant patterns have values less than or

equal to 0, whereas normal patterns have values greater than or equal to 0.50.

Nonlinear separable problems are transformed into linear ones by projecting data into feature space and then finding the ideal separate hyperplane for the support vector machine classifier. The study uses the characteristics of handcrafted goods to predict consumer behavior.

Overfitting can be minimized and performance improved by combining multiple decision trees into a single decision tree in a random forest. Highdimensional data can be handled by the RF classifier while yet preserving a high level of efficiency.

Gradient Boosting Decision Tree is an iterative strategy that consists of several decision trees. A majority vote is used in both random forests and the general Bayesian decision tree (GBDT), however the GBDT adds up each outcome or weight individually.

In contrast to the suggested method, CNN, CNN-GBDT, and CNN-SVM use softmax in the final layer.

V.Implementation and Results

Step 1:import libraries:

```
from tkinter import *
import tkinter
from tkinter import filedialog
import numpy as np
from tkinter.filedialog import askopenfilename
import pandas as pd
from tkinter import simpledialog
import pandas as pd
import numpy as np
from sklearn.preprocessing import LabelEncoder
from sklearn.preprocessing import normalize
from tensorflow.keras.models import Sequential, Model
from tensorflow.keras.layers import Dense, Dropout, Activation
from tensorflow.keras.utils import to categorical
from tensorflow.keras.models import model from json
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import precision_score
from sklearn.metrics import recall score
from sklearn.metrics import f1_score
from sklearn.metrics import accuracy score
from sklearn.model_selection import train_test_split
from sklearn import svm
import os
import matplotlib.pyplot as plt
```

(where tkinter used for GUI(front end), pandas - data preprocessing, numpy - mathematical, matplotlib - data visualization, sklearn - machine learning, tensorflow and keras - machine learning and AI back end purpose)

Step 2: Defining the main function and setting the title & size of tkinter

main = tkinter.Tk()
main.title("Electricity Theft Detection in Power Grids with Deep Learning and Random Forests")
main.geometry("10006450")

Step 3: Defining the global function

```
global filename
global cnn_model
global X, Y
global le
global dataset
accuracy = []
precision = []
recall = []
fscore = []
global classifier
```

Step 4: Defining the upload function

```
def uploadDataset():
    global filename
    global dataset
    filename = filedialog.askopenfilename(initialdir = "Dataset")
    text.delete('1.0', END)
    text.insert(END,filename+' Loaded\n')
    dataset = pd.read_csv(filename)
    text.insert(END,str(dataset.head())+"\n\n")
```

Step 5:Defining the preprocess Data set function

```
def preprocessBataset():
    global X, Y
    global le
    global dataset
    le = tabelincode()
    text.delte('1.0', ERD)
    dataset['line() influes = True)
    dataset['line() influes = True)
    dataset['line() influes = True)
    dataset('line('line('line('line('line('l)
    print(dataset.info())
    dataset('line('line('line('line('line('l)
    dataset('line('line('line('line('line('line('l)
    random.shuffle(indices)
    x = Xindices|
    x = X
```

Model building

Step 6: CNN	
<pre>def runCNN(): global X, Y global x, Y text.delate(11.0', END) global cnn_model acuracy.clear() precision.clear() fracore.clear() Y1 = co_categorical(Y) Y1 = to_categorical(Y) Y1 = to_categorical(Y) forn_model.clear() cnn_model.clear() forn_model.jsumary() print(cnn_model.sumary())</pre>	

Step 7: CNNRF

def	runCNNRF():
	global classifier
	global X, Y
	global cnn model
	predict = cnn model.predict(X)
	xy = [1]
	for in range(len(predict)):
	val = np.aromax(predict[i])
	YX.append(val)
	YI = np.asarray(YI)
	extract = Model(cnn model.inputs, cnn model.layers[-2].output)
	<pre>extract = model(inf_model.inputs, cnf_model.ingers[-z].output) XX = extract.predict(X)</pre>
	<pre>rfc = RandomForestClassifier(n_estimators=200, random_state=0)</pre>
	rfc.fit(XX, YY)
	classifier = rfc
	<pre>X_train, X_test, y_train, y_test = train_test_split(XX, YY, test_size=0.2, random_state=0)</pre>
	<pre>predict = rfc.predict(X_test)</pre>
	<pre>p = precision_score(y_test, predict,average='macro') * 100</pre>
	r = recall_score(y_test, predict, average='macro') * 100
	<pre>f = f1_score(y_test, predict, average='macro') * 100</pre>
	a = accuracy_score(y_test,predict)*100
	accuracy.append(a)
	precision.append(p)
	recall.append(r)
	fscore.append(f)
	text, insert (END, "CNN with Random Forest Precision : "+str(p)+"\n")
	text.insert(END, "CNN with Random Forest Recall : "+str(r)+"\n")
	text, insert (END, "CNN with Random Forest FMeasure : "+str(f)+"\n")
	text.insert(END, "CNN with Random Forest Accuracy : "+str(f)+"\n\n")
	energine, our stor manage recently . Ther (1/1 / 1/1/)

Step 8: CNNSVM

def runCNNEYN(): global X, Y global cn_model predict = cnm_model.predict(X) YT = [] for i in range[len(predict)]: val = pa.sgmax[pecifc1]] YT.append(val) YT = np.asgmax[pecifc1]] YT = np.asgmax[pecifc1]] variant = Model(cnm_model.inputs, cnm_model.layers[-2].output) xtraint = Xtraint

Step 9:Random Forest

isf runandmePorest():
 global X, Y
 X train, X_test, <u>1</u> train, y_test = train_test_split(X, Y, test_size=0.2, random_state=0)
 rfc = RandmePorestClassifier(n_estimators=200, random_state=0)
 rfc.fit(X_train, y_train)
 predict = rfc.predict(X_test)
 p = precision_accore(y_test, predict, average='macro') * 100
 r = recall_accore(y_test, predict, average='macro') * 100
 a = accuracy_accore(y_test, predict, average='macro') * 100
 a = accuracy_accore(y_test, predict, average='macro') * 100
 accuracy_accore(y_test, predict)*100
 accuracy_accore(y_test, average='macro')*100
 accuracy_accore(y_test, predict)*100
 accuracy_accore(y_test, predict)*100
 accuracy_accore(y_test, predict)*100
 accuracy_accore(y_test, predict)*100
 accuracy_acuracy_acuracy_accuracy_accuracy

Step 10: SVM

```
er rubsw0():
global x, Y
X_train, X_tet, y_train, y_test = train_test_split(X, Y, test_size=0.2, random_state=0)
rfc = swm.SV()
rfc fit(X_train, y_train)
predict = rfc.predict(X_test)
p = precision_score(y_test, predict, average="macro") * 100
r = recall_score(y_test, predict, average="macro") * 100
a = accuracy_score(y_test, predict, average="macro") * 100
a = accuracy_score(y_test, predict, average="macro") * 100
a = accuracy_score(y_test, predict, average="macro") * 100
accuracy_append(a)
pecall_append(1)
fscore.append(f)
text.insert(EMD,"SVM Facil : "+str(p)+"\n")
text.insert(EMD,"SVM Recall : "+str(p)+"\n")
text.insert(EMD,"SVM Accuracy : "+str(f)+"\n")
```

Step 11:Defining prediction function

```
def predict():
    global classifier
    global cn_model
    text.delete('1.0', END)
    filename = filedialog.askopenfilename(initialdir = "Dataset")
    test = pd.read csv(filename)
    test = dr.ead csv(filename)
    test = test.values
    data = test
    extract = Model(cnn model.inputs, cnn_model.layers[-2].output)
    test = extract.predict(test)
    predict = classifier.predict(test)
    for i in range[len[predict]):
        if predict[i] == 1:
            test.insert(END,str(data[i])+" ===> record detected as ENERGY THEFT\n\n")
        if predict[i] == 0:
            test.insert(END,str(data[i])+" ===> record NOT detected as ENERGY THEFT\n\n")
```

Step 12: Accuracy comparison graph

def graph():

df = pd.BataFrame([['OW', 'Precision', precision[0]], ['OW', 'Recall', recall[0]], ['OW', 'F! Score', fscore[0]], ['OW', 'Accuracy', accc ['OW-FR', 'Precision', precision[2]], ['OW-FR', 'Recall', recall[2]], ['OW-FR', 'F! Score', fscore[2]], ['OW-FR', 'Recall', recall[2]], ['OW-FR', 'F! CONCLUSION

A new CNN-RF model for detecting electricity theft is provided in this research. In this architecture, the CNN serves as a feature extractor similar to a smart meter data analyzer, while the RF serves as a classifier for the results. In order to avoid overfitting, a fully linked layer with a dropout rate of 0.4 is developed during the training phase of the process. SMOT is also employed to address the issue of data imbalance. SVM, RF, GBDT, and LR are just a few of the deep learning and machine learning approaches that have been tested on the SEAI and LCL datasets. Due to two characteristics, the suggested CNN-RF model appears to be a promising classification method for the detection of electricity theft: Hybrid models can automatically extract features from a dataset, whereas standard classifiers rely heavily on hand-designed features, which is a time and laborintensive process. Another advantage of the hybrid model is that it incorporates the most widely used and successful classifiers for detecting electricity theft, RF and CNN.

Aiming for the Future:

Detection of electricity theft has an impact on the privacy of consumers. Future research will look into how the granularity and duration of data collected by smart meters affects that confidentiality. Using the hybrid CNN-RF model for additional purposes (such as load forecasting) is something that should be investigated further.
